

Intuitionistic epistemic logic categorically and algebraically

Daniel Rogozin

University College London

Seminar on Programming principles, Logic and Verification

The 24th of March 2023

Introduction

Intuitionistic modal logic: the big picture

- As it is well known, modal logic extends classical logic with modal operators.
- Applications: topology, proof theory, formal verification, ontologies, etc.
- Intuitionistic modal logic is a version of modal logic where the underlying logic is the intuitionistic one.
- Possible topics where intuitionistic modal logic is of interest:
 - Constructive necessity, provability in intuitionistic arithmetic, intuitionistic knowledge, etc.
 - Model theory: the finite model property, canonicity à la Salqvist, definability à la Thomason-Goldblatt, etc.
 - Representation theory: general descriptive frames, Esakia duality, etc.

Intuitionistic modal logic: the big picture

 - Model theory: the finite model property, canonicity à la Salqvist, definability à la Thomason-Goldblatt, etc.
 - Representation theory: general descriptive frames, Esakia duality, etc.

See this summary paper to have the big picture in more detail

- Frank Wolter and Michael Zakharyashev. Intuitionistic Modal Logic, 1999.

- Type theory deals with a computation every value in which is annotated with the corresponding data type. Type theory is closely connected with intuitionistic logic and constructive proofs through the Curry-Howard correspondence.
- One can extend Curry-Howard to intuitionistic modal logic and study modal operators within the “types-as-formulas” and “proofs-as-terms” paradigm.
- Here we think of modal types as abstract data types of action, which are of interest for functional programming.

Modalities type theoretically

- Type theory deals with a computation every value in which is annotated with the corresponding data type. Type theory is closely connected with intuitionistic logic and constructive proofs through the Curry-Howard correspondence.
- One can extend Curry-Howard to intuitionistic modal logic and study modal operators within the “types-as-formulas” and “proofs-as-terms” paradigm.
- Here we think of modal types as abstract data types of action, which are of interest for functional programming.

Modal type theory based on IEL⁻

The definition of the type theory

The modal lambda calculus λ_{IEL} is axiomatised with the following inference rules.

$$\frac{}{\Gamma, x : \varphi \vdash x : \varphi} \text{ ax}$$

$$\frac{\Gamma, x : \varphi \vdash M : \psi}{\Gamma \vdash \lambda x. M : \varphi \rightarrow \psi} \rightarrow_i$$

$$\frac{\Gamma \vdash M : \varphi \rightarrow \psi \quad \Gamma \vdash N : \varphi}{\Gamma \vdash MN : \psi} \rightarrow_e$$

$$\frac{\Gamma \vdash M : \varphi \quad \Gamma \vdash N : \psi}{\Gamma \vdash \langle M, N \rangle : \varphi \times \psi} \times_i$$

$$\frac{\Gamma \vdash M : \varphi_1 \times \varphi_2}{\Gamma \vdash \pi_i M : \varphi_i} \times_e, i = 1, 2$$

$$\frac{\Gamma \vdash M : \varphi}{\Gamma \vdash \text{pure } M : \bigcirc \varphi} \bigcirc_I$$

$$\frac{\Gamma \vdash \vec{M} : \bigcirc \vec{\varphi} \quad \vec{x} : \vec{\varphi} \vdash N : \psi}{\Gamma \vdash \text{let } \bigcirc \vec{x} = \vec{M} \text{ in } N : \bigcirc \psi} \text{let}_{\bigcirc}$$

The reduction rules are defined with the following rewriting rules:

1. $(\lambda x.M)N \rightarrow_{\beta} M[x := N]$.
2. $\pi_1 \langle M, N \rangle \rightarrow_{\beta} M$.
3. $\pi_2 \langle M, N \rangle \rightarrow_{\beta} N$.
4. **let** $\bigcirc \vec{x}, y, \vec{z} = \vec{M}$, **let** $\bigcirc \vec{w} = \vec{N}$ **in** Q, \vec{P} **in** $R \rightarrow_{\beta}$ **let** $\bigcirc \vec{x}, \vec{w}, \vec{z} = \vec{M}, \vec{N}, \vec{P}$ **in** $R[y := Q]$.
5. **let** $\bigcirc \vec{x} = \text{pure } \vec{M}$ **in** $N \rightarrow_{\beta}$ **pure** $N[\vec{x} := \vec{M}]$.
6. **let** $\bigcirc _ = _$ **in** $M \rightarrow_{\beta}$ **pure** M , where $_$ is an empty sequence of terms.

The reduction rules are defined with the following rewriting rules:

1. $(\lambda x.M)N \rightarrow_{\beta} M[x := N]$.
2. $\pi_1 \langle M, N \rangle \rightarrow_{\beta} M$.
3. $\pi_2 \langle M, N \rangle \rightarrow_{\beta} N$.
4. **let** $\bigcirc \vec{x}, y, \vec{z} = \vec{M}$, **let** $\bigcirc \vec{w} = \vec{N}$ **in** Q, \vec{P} **in** $R \rightarrow_{\beta}$ **let** $\bigcirc \vec{x}, \vec{w}, \vec{z} = \vec{M}, \vec{N}, \vec{P}$ **in** $R[y := Q]$.
5. **let** $\bigcirc \vec{x} = \text{pure } \vec{M}$ **in** $N \rightarrow_{\beta}$ **pure** $N[\vec{x} := \vec{M}]$.
6. **let** $\bigcirc _ = _$ **in** $M \rightarrow_{\beta}$ **pure** M , where $_$ is an empty sequence of terms.

The multistep reduction \rightarrow_{β} is reflexive-transitive closure of \rightarrow_{β} .

Theorem (D.R. 2018)

1. (Type preservation)

If $\Gamma \vdash M : \varphi$ and $M \rightarrow_{\beta} N$, then $\Gamma \vdash N : \varphi$

2. (Strong normalisation)

Every reduction path terminates, that is, no infinite reduction sequences.

3. (Church-Rosser)

If $M \rightarrow_{\beta} N_1, N_2$, then there exists P such that $N_1, N_2 \rightarrow_{\beta} P$.

As a corollary, every $\lambda_{\text{IEL-term}}$ has a unique normal form.

Categorical completeness

Category theory

Now I am going to be like the guy from the right.

Normie:	An intellectual whomst'd've hath learneth category theory:
	
- group	- isomorphism category on a single object
- kernel	- an equalizer object of f to the zero morphism
- tensor product	- left adjoint functor of Hom in monoidal categories
- simplicial complex	- n -homotopy structure over a locally small category
- homology	- \mathbb{Z} -indexed family of functors to Abelian category subject to Eilenberg-Steenrod axioms
- empty set	- an initial object in a boolean Lawvere-Tierney topos
- diagram	- covariant functor from some fixed indexing category
- smooth manifold	- object in a category of locally representable sheaves on category of cartesian spaces
- R -algebra	- a pointed one-object category enriched over $(R\text{Mod}, \otimes)$

General concepts: Category

Recall that a category \mathcal{C} consists of:

- A class of objects $\text{Ob}(\mathcal{C}) = \{A, B, C, \dots\}$,
- A class of morphisms $\mathcal{C}(A, B)$ for each $A, B \in \text{Ob}(\mathcal{C})$, where $f : A \rightarrow B$ iff $f \in \mathcal{C}(A, B)$,
- For $f : A \rightarrow B$ and $g : B \rightarrow C$, then $g \circ f : A \rightarrow C$ and $h \circ (g \circ f) = (h \circ g) \circ f$ for each f, g, h having an appropriate domain and codomain,
- For each $A, B \in \text{Ob}(\mathcal{C})$ we have identity morphisms such that for each $f : A \rightarrow B$ $f \circ \text{id}_A = f$ and $\text{id}_B \circ g = g$.

Some examples:

- **Set**, the category of all sets and all functions between them,
- **Top**, the category of all topological spaces and continuous maps,
- **Vect_k**, the category of vector spaces over a field k and linear maps,
- (P, \leq) , any poset where $a \rightarrow b$ exists iff $a \leq b$,
- Any monoid (as well as a group) is a category, where $\text{Ob}(\mathcal{C})$ is a singleton set (Cayley's theorem).
- etc.

General concepts: Functor

Intuitively, a functor is a morphism of category. Rigorously, let \mathcal{C} and \mathcal{D} be categories, a functor $\mathbf{F} : \mathcal{C} \rightarrow \mathcal{D}$ is a “function” such that:

- Each $A \in \text{Ob}(\mathcal{C})$ maps to $\mathbf{F}A \in \text{Ob}(\mathcal{D})$,
- Each $f : A \rightarrow B$ in \mathcal{C} maps to $\mathbf{F}f : \mathbf{F}A \rightarrow \mathbf{F}B$ in \mathcal{D} ,
- $\mathbf{F}(id_A) = id_{\mathbf{F}A}$
- $\mathbf{F}(g \circ f) = \mathbf{F}g \circ \mathbf{F}f$ for each f and g .

Some examples:

- The powerset functor $\mathcal{P} : \mathbf{Set} \rightarrow \mathbf{Set}$ such that $\mathcal{P} : A \mapsto 2^A$,
- The abelianisation functor $Ab : \mathbf{Group} \rightarrow \mathbf{Ab}$ such that $Ab : G \mapsto G/[G, G]$,
- The spectrum functor $\text{Spec} : \mathbf{Ring}^{op} \rightarrow \mathbf{Top}$ that maps every commutative ring to its Zariski space,
- $\mathbf{Field} \rightarrow \mathbf{Ring}$ such that $k \mapsto k[X]$,
- $\pi_1 : \mathbf{Top}_* \rightarrow \mathbf{Group}$ maps every topological space with a base point to its fundamental group, for example, $\pi_1(S) = \mathbb{Z}$ (up to isomorphism).
- etc.

General concepts: Natural transformation

A natural transformation is a functor morphism. Let \mathcal{C}, \mathcal{D} be categories and $\mathbf{F}, \mathbf{G} : \mathcal{C} \rightarrow \mathcal{D}$ functors. A natural transformation $\theta : \mathbf{F} \Rightarrow \mathbf{G}$ is a collection of morphisms $\theta_A : \mathbf{F}A \rightarrow \mathbf{G}A$ in \mathcal{D} making the following square commute for each $f : A \rightarrow B$ and $A, B \in \text{Ob}(\mathcal{C})$:

$$\begin{array}{ccc} \mathbf{F}A & \xrightarrow{\mathbf{F}f} & \mathbf{F}B \\ \theta_A \downarrow & & \downarrow \theta_B \\ \mathbf{G}A & \xrightarrow{\mathbf{G}f} & \mathbf{G}B \end{array}$$

General concepts: Natural transformation

A natural transformation is a functor morphism. Let \mathcal{C}, \mathcal{D} be categories and $\mathbf{F}, \mathbf{G} : \mathcal{C} \rightarrow \mathcal{D}$ functors. A natural transformation $\theta : \mathbf{F} \Rightarrow \mathbf{G}$ is a collection of morphisms $\theta_A : \mathbf{F}A \rightarrow \mathbf{G}A$ in \mathcal{D} making the following square commute for each $f : A \rightarrow B$ and $A, B \in \text{Ob}(\mathcal{C})$:

$$\begin{array}{ccc} \mathbf{F}A & \xrightarrow{\mathbf{F}f} & \mathbf{F}B \\ \theta_A \downarrow & & \downarrow \theta_B \\ \mathbf{G}A & \xrightarrow{\mathbf{G}f} & \mathbf{G}B \end{array}$$

An example:

Let \det_M be the determinant of the $n \times n$ matrix $M \in \text{GL}_n k$ with entries from a field k and k^* is the multiplicative group of k . Both GL_n and $*$ are functors from the category of fields to the category of groups, and $\det_M : \text{GL}_n k \rightarrow k^*$ is a morphism of groups and it is natural:

$$\begin{array}{ccc} \text{GL}_n k & \xrightarrow{f} & \text{GL}_n k' \\ \det_M \downarrow & & \downarrow \det_{M'} \\ k^* & \xrightarrow{f^*} & k'^* \end{array}$$

Cartesian closed categories

A category is *cartesian closed* if there are objects $\mathbb{1}$, B^A and $A \times B$ such that:

- $|\mathcal{C}(A, \mathbb{1})| = 1$ for each $A \in \text{Ob}(\mathcal{C})$,
- The following diagrams commute:

The second diagram can be reformulated as (compare with the definition of implication in Heyting algebras):

$$\mathcal{C}(A \times B, C) \simeq \mathcal{C}(A, C^B)$$

Cartesian closed categories

A category is *cartesian closed* if there are objects $\mathbb{1}$, B^A and $A \times B$ such that:

- $|\mathcal{C}(A, \mathbb{1})| = 1$ for each $A \in \text{Ob}(\mathcal{C})$,
- The following diagrams commute:

The second diagram can be reformulated as (compare with the definition of implication in Heyting algebras):

$$\mathcal{C}(A \times B, C) \simeq \mathcal{C}(A, C^B)$$

Some examples:

- **Set**,
- Every Heyting algebra,
- The category of G -sets for a group G (the category of group actions),
- The category of simplicial sets (which are also contravariant functors $\Delta : \omega \rightarrow \mathbf{Set}$).

Typed lambda calculi type-theoretically

Cartesian closed categories allow interpreting intuitionistic type theories using the following scheme:

$\Gamma \models M : A$ iff there exists an arrow $\llbracket M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket A \rrbracket$.

Typed lambda calculi type-theoretically

Cartesian closed categories allow interpreting intuitionistic type theories using the following scheme:

$$\Gamma \models M : A \text{ iff there exists an arrow } \llbracket M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket A \rrbracket.$$

In particular, simply typed lambda calculus with types \rightarrow and \times has the following interpretation in CCCs.

$$\begin{array}{c} \frac{}{\llbracket \Gamma, x : \varphi \vdash x : \varphi \rrbracket = \pi_2 : \llbracket \Gamma \rrbracket \times \llbracket \varphi \rrbracket \rightarrow \llbracket \varphi \rrbracket} \\[10pt] \frac{\llbracket \Gamma, x : \varphi \vdash M : \psi \rrbracket = \llbracket M \rrbracket : \llbracket \Gamma \rrbracket \times \llbracket \varphi \rrbracket \rightarrow \llbracket \psi \rrbracket}{\llbracket \Gamma \vdash (\lambda x.M) : \varphi \rightarrow \psi \rrbracket = \widehat{(\llbracket M \rrbracket)} : \llbracket \Gamma \rrbracket \rightarrow \llbracket \psi \rrbracket^{\llbracket \varphi \rrbracket}} \\[10pt] \frac{\llbracket \Gamma \vdash M : \varphi \rightarrow \psi \rrbracket = \llbracket M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \psi \rrbracket^{\llbracket \varphi \rrbracket} \quad \llbracket \Gamma \vdash N : \varphi \rrbracket = \llbracket N \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \varphi \rrbracket}{\llbracket \Gamma \vdash (MN) : \psi \rrbracket = \llbracket \Gamma \rrbracket \xrightarrow{([M], [N])} \llbracket \psi \rrbracket^{\llbracket \varphi \rrbracket} \times \llbracket \varphi \rrbracket \xrightarrow{ev} \llbracket \psi \rrbracket} \\[10pt] \frac{\llbracket \Gamma \vdash M : \varphi \rrbracket = \llbracket M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \varphi \rrbracket \quad \llbracket \Gamma \vdash N : \psi \rrbracket = \llbracket N \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket B \rrbracket}{\llbracket \Gamma \vdash (M, N) : \varphi \times \psi \rrbracket = (\llbracket M \rrbracket, \llbracket N \rrbracket) : \llbracket \Gamma \rrbracket \rightarrow \llbracket \varphi \rrbracket \times \llbracket \psi \rrbracket} \\[10pt] \frac{\llbracket \Gamma \vdash M : \varphi_1 \times \varphi_2 \rrbracket = \llbracket M \rrbracket : \llbracket \Gamma \rrbracket \rightarrow \llbracket \varphi_1 \rrbracket \times \llbracket \varphi_2 \rrbracket}{\llbracket \Gamma \vdash \pi_i M : \varphi_i \rrbracket = \llbracket \Gamma \rrbracket \xrightarrow{[M]} \llbracket \varphi_1 \rrbracket \times \llbracket \varphi_2 \rrbracket \xrightarrow{\pi_i} \llbracket \varphi_i \rrbracket} \quad i \in \{1, 2\} \end{array}$$

Monoidal endofunctors as modalities

We are interested in how to interpret \Box -like modality categorically. Recall that one reformulate the **K** axioms of \Box the following way:

- (The multiplicativity axiom)

$$\Box(p \wedge q) \leftrightarrow \Box p \wedge \Box q$$

- (The normality axiom)

$$\Box \top \leftrightarrow \top$$

- (The monotonicity rule)

From $\varphi \rightarrow \psi$ infer $\Box \varphi \rightarrow \Box \psi$

Monoidal endofunctors as modalities

We are interested in how to interpret \Box -like modality categorically. Recall that one reformulate the **K** axioms of \Box the following way:

- (The multiplicativity axiom)

$$\Box(p \wedge q) \leftrightarrow \Box p \wedge \Box q$$

- (The normality axiom)

$$\Box \top \leftrightarrow \top$$

- (The monotonicity rule)

$$\text{From } \varphi \rightarrow \psi \text{ infer } \Box \varphi \rightarrow \Box \psi$$

Categorically, we have an endofunctor $F : \mathcal{C} \rightarrow \mathcal{C}$ with the following natural isomorphisms (this is a *strong monoidal endofunctor*):

- $m_{A,B} : F(A \times B) \cong FA \times FB$
- $u : F\mathbb{1} \cong \mathbb{1}$

Monoidal endofunctors as modalities

We are interested in how to interpret \Box -like modality categorically. Recall that one reformulate the **K** axioms of \Box the following way:

- (The multiplicativity axiom)

$$\Box(p \wedge q) \leftrightarrow \Box p \wedge \Box q$$

- (The normality axiom)

$$\Box \top \leftrightarrow \top$$

- (The monotonicity rule)

$$\text{From } \varphi \rightarrow \psi \text{ infer } \Box \varphi \rightarrow \Box \psi$$

Categorically, we have an endofunctor $F : \mathcal{C} \rightarrow \mathcal{C}$ with the following natural isomorphisms (this is a *strong monoidal endofunctor*):

- $m_{A,B} : F(A \times B) \cong FA \times FB$
- $u : F\mathbb{1} \cong \mathbb{1}$

The modal lambda calculus Curry-Howard isomorphic to the intuitionistic modal logic **K** with \Box is known to sound and complete w.r.t. CCCs with strong monoidal endofunctors.

See

\mathbf{IEL}^- as a natural transformation

To interpret the \mathbf{IEL}^- we need the natural transformation $\eta : Id_{\mathcal{C}} \Rightarrow \mathbf{F}$, where \mathcal{C} is a CCC and F is a strong monoidal endofunction with the additional principles:

1. $u = \eta_{\mathbb{1}}$
2. For each $A, B \in \text{Ob}(\mathcal{C})$:

$$\begin{array}{ccc} A \times B & \xrightarrow{\eta_A \times \eta_B} & \mathbf{F}A \times \mathbf{F}B \\ & \searrow \eta_{A \times B} & \downarrow m_{A,B} \\ & & \mathbf{F}(A \times B) \end{array}$$

IEL⁻ as a natural transformation

To interpret the **IEL⁻** we need the natural transformation $\eta : Id_{\mathcal{C}} \Rightarrow \mathbf{F}$, where \mathcal{C} is a CCC and F is a strong monoidal endofunctor with the additional principles:

1. $u = \eta_{\mathbb{1}}$
2. For each $A, B \in \text{Ob}(\mathcal{C})$:

$$\begin{array}{ccc} A \times B & \xrightarrow{\eta_A \times \eta_B} & \mathbf{F}A \times \mathbf{F}B \\ & \searrow \eta_{A \times B} & \downarrow m_{A,B} \\ & & \mathbf{F}(A \times B) \end{array}$$

An **IEL⁻-category** is a triple $(\mathcal{C}, \mathbf{F}, \eta)$, where \mathcal{C} is a CCC, \mathbf{F} is a strong monoidal endofunctor and $\eta : Id_{\mathcal{C}} \Rightarrow \mathbf{F}$ is a natural transformation with the additional extra-principles as above.

IEL⁻ as a natural transformation

To interpret the **IEL⁻** we need the natural transformation $\eta : Id_{\mathcal{C}} \Rightarrow \mathbf{F}$, where \mathcal{C} is a CCC and F is a strong monoidal endofunction with the additional principles:

1. $u = \eta_{\mathbb{1}}$
2. For each $A, B \in \text{Ob}(\mathcal{C})$:

$$\begin{array}{ccc} A \times B & \xrightarrow{\eta_A \times \eta_B} & \mathbf{F}A \times \mathbf{F}B \\ & \searrow \eta_{A \times B} & \downarrow m_{A,B} \\ & & \mathbf{F}(A \times B) \end{array}$$

An **IEL⁻-category** is a triple $(\mathcal{C}, \mathbf{F}, \eta)$, where \mathcal{C} is a CCC, \mathbf{F} is a strong monoidal endofunctor and $\eta : Id_{\mathcal{C}} \Rightarrow \mathbf{F}$ is a natural transformation with the additional extra-principles as above.

Theorem (D. R. 2018)

If M and N are well-typed and $M =_{\beta} N$, then $\llbracket M \rrbracket = \llbracket N \rrbracket$. That is, λ_{IEL^-} is sound and complete w.r.t. **IEL⁻**-categories.

We skip the complete argument, but we just show how to interpret the modal inference rules in \mathbf{IEL}^- -categories:

$$\frac{[\Gamma \vdash M : \bigcirc \varphi] = [M] : [\Gamma] \rightarrow [\varphi]}{[\Gamma \vdash \mathbf{pure} \ M : \bigcirc \varphi] = [M] \circ \eta_{[\varphi]} : [\Gamma] \rightarrow \mathbf{F}[\varphi]}$$

$$\frac{[\Gamma \vdash \vec{M} : \bigcirc \vec{\varphi}] = ([M_1], \dots, [M_n]) : [\Gamma] \rightarrow \prod_{i=1}^n \mathbf{F}[\varphi_i] \quad [\vec{X} : \vec{\varphi} \vdash N : \psi] = [N] : \prod_{i=1}^n [\varphi_i] \rightarrow [\psi]}{[\Gamma \vdash \mathbf{let} \ \bigcirc \vec{X} = \vec{M} \ \mathbf{in} \ N : \bigcirc \psi] = \mathbf{F}([N]) \circ m_{[\varphi_1], \dots, [\varphi_n]} \circ ([M_1], \dots, [M_n]) : [\Gamma] \rightarrow \mathbf{F}[\psi]}$$

We skip the complete argument, but we just show how to interpret the modal inference rules in \mathbf{IEL}^- -categories:

$$\frac{[\Gamma \vdash M : \bigcirc \varphi] = [M] : [\Gamma] \rightarrow [\varphi]}{[\Gamma \vdash \mathbf{pure} \ M : \bigcirc \varphi] = [M] \circ \eta_{[\varphi]} : [\Gamma] \rightarrow \mathbf{F}[\varphi]}$$

$$\frac{[\Gamma \vdash \vec{M} : \bigcirc \vec{\varphi}] = ([M_1], \dots, [M_n]) : [\Gamma] \rightarrow \prod_{i=1}^n \mathbf{F}[\varphi_i] \quad [\vec{X} : \vec{\varphi} \vdash N : \psi] = [N] : \prod_{i=1}^n [\varphi_i] \rightarrow [\psi]}{[\Gamma \vdash \mathbf{let} \ \bigcirc \vec{X} = \vec{M} \ \mathbf{in} \ N : \bigcirc \psi] = \mathbf{F}([N]) \circ m_{[\varphi_1], \dots, [\varphi_n]} \circ ([M_1], \dots, [M_n]) : [\Gamma] \rightarrow \mathbf{F}[\psi]}$$

The interpretation of the second inference rule could be also described via the (slightly modified) quote from Hamlet:

*Therefore, since brevity is the soul of wit
and tediousness the limbs and outward flourishes,
I won't be brief.*

Kripke-Joyal semantics

Some background: Heyting algebras and locales

Recall that a Heyting algebra is a bounded distributive lattice $\mathcal{H} = (H, \wedge, \vee, \rightarrow, 0, 1)$ with the operation \rightarrow satisfying for all $a, b, c \in H$:

$$a \wedge b \leq c \text{ iff } a \leq b \rightarrow c$$

A locale is a complete lattice $\mathcal{L} = (L, \wedge, \bigvee)$ satisfying for all $a \in L$ and for each indexed family $(a_i)_{i \in I}$:

$$a \wedge \bigvee_{i \in I} a_i = \bigvee_{i \in I} (a \wedge a_i)$$

Some background: Heyting algebras and locales

Recall that a Heyting algebra is a bounded distributive lattice $\mathcal{H} = (H, \wedge, \vee, \rightarrow, 0, 1)$ with the operation \rightarrow satisfying for all $a, b, c \in H$:

$$a \wedge b \leq c \text{ iff } a \leq b \rightarrow c$$

A locale is a complete lattice $\mathcal{L} = (L, \wedge, \bigvee)$ satisfying for all $a \in L$ and for each indexed family $(a_i)_{i \in I}$:

$$a \wedge \bigvee_{i \in I} a_i = \bigvee_{i \in I} (a \wedge a_i)$$

Heyting algebras and locales are about:

- Heyting algebras provide algebraic semantics for intuitionistic and intermediate logics,
- Locales are a lattice-theoretic approximation of topological spaces,
- Subobject algebras in topoi

Some background: Heyting algebras and locales
